

## A2 NETWORKS · A2.3

# Data transmissions

How data moves across a network: **IP addressing**, the **media** it travels through, **packet switching**, and static vs dynamic **routing**.

## 01 IP addressing

|                |                                        |
|----------------|----------------------------------------|
| <b>IPv4</b>    | 32-bit, dotted decimal (192.168.0.1).  |
| <b>IPv6</b>    | 128-bit, hexadecimal, colon-separated. |
| <b>Public</b>  | Globally unique, internet-routable.    |
| <b>Private</b> | LAN only (192.168.x.x); NAT to public. |
| <b>Static</b>  | Fixed, manual (servers).               |
| <b>Dynamic</b> | DHCP-assigned, can change.             |

## 02 Transmission media

|                     |                                                     |
|---------------------|-----------------------------------------------------|
| <b>Fibre</b>        | Light in glass; fast, long, immune to interference. |
| <b>Twisted pair</b> | Copper pairs; cheap LAN cabling (UTP/STP).          |
| <b>Coaxial</b>      | Shielded copper core; cable broadband.              |
| <b>Wireless</b>     | Radio waves; mobile, but least secure.              |

## 03 Packet switching

### 01

#### Segmentation

Data is split into numbered packets, each wrapped with a header (encapsulation): source IP, dest IP, sequence number.

### 02

#### Routing

Routers forward each packet by the best path, so packets can take different routes and arrive out of order.

### 03

#### Reassembly

Headers are stripped (de-encapsulation) and sequence numbers put the packets back in order.

**04 Routing**

● **Static**

Routes set manually and fixed. Simple and predictable, but does not adapt if a link fails.

● **Dynamic**

Routers update routing tables automatically to find the best path. Resilient and scalable, but complex.

**05 Key terms**

**Packet** Header + payload.

**Header** Source IP, dest IP, sequence number.

**Payload** A chunk of the actual data.

**Encapsulation** Adding the header before sending.

**NAT** Many private addresses to one public.

**DHCP** Hands out dynamic IP addresses.

**06 Know the difference**

**IPv4 vs IPv6**

32-bit dotted decimal (~4.3 billion) versus 128-bit hexadecimal (~340 undecillion).

**ADDRESSING**

**Public vs private**

Internet-routable and globally unique versus LAN-only; NAT bridges the two.

**SCOPE**

**Static vs dynamic IP**

Fixed and manually set versus assigned automatically by DHCP and able to change.

**ASSIGNMENT**

**Packet vs circuit**

Independent packets on any route versus one dedicated path reserved for the whole transmission.

**SWITCHING**

## FINAL PASS BEFORE THE EXAM

## Rapid exam tips

Eight things that lose marks in Paper 1 if you slip on them. Skim before you walk in.

**01**

**IPv4** is 32-bit; **IPv6** is 128-bit. Don't swap the bit sizes.

**02**

Private IPs (192.168.x.x) are **not** internet-routable; **NAT** bridges to public.

**03**

Static/dynamic **IP** is not the same as static/dynamic **routing**.  
Two different uses.

**04**

In packet switching, packets can take **different routes** and arrive out of order.

**05**

A packet's **header** holds source IP, dest IP, and sequence number; the **payload** is the data.

**06**

**Fibre** is fast and immune to interference; **wireless** is the least secure medium.

**07**

**Static routing** is manual and fixed; **dynamic routing** adapts via routing tables.

**08**

Packet switching is not **circuit switching**: no single path is reserved end to end.
